(54) Titre: LIGNEE MONOCELLULAIRE DE CELLULES DE SPODOPTERA FRUGIPERDA EN SUSPENSION DANS UN MILIEU EXEMPT DE SERUM, ET SES PROCÉDES D'OBTENTION ET D'UTILISATION

(57) Abstract

Disclosed and claimed is a new insect cell line, Sf900+, ATCC CRL-12579. The insect cell line was established from Lepidoptera, Noctuidae, Spodoptera frugiperda Sf-9 (ATCC CRL-1771) through multiple rounds of limiting dilution and selection in a serum-free insect medium supplemented with added human insulin. The insect cell line is useful in BEVS or as an adjuvant and has many characteristics and advantages. Also disclosed and claimed are recombinant proteins from recombinant baculovirus expression in insect cells such as Sf900+ cells, for instance, HA, NA, EPO, CD4, CEA, and thrombospondin.

(57) Abrégé

L'invention porte sur une nouvelle lignée de cellules d'insectes, la Sf900+, ATCC CRL-12579, obtenue à partir de Lepidoptera, Noctuidae, Spodoptera frugiperda Sf-9 (ATCC CRL-1771) par une suite de dilutions limitatrices et de sélections dans un milieu d'insectes additionné d'insuline humaine. Cette lignée de cellules d'insectes est utile dans le BEVS (système d'expression du baculovirus) ou comme adjuvant présente de nombreuses caractéristiques et avantages. L'invention porte également sur des protéines de recombinaison provenant de l'expression de baculovirus dans des cellules d'insectes telles que les cellules Sf900+, par exemple HA, NA, EPO, CD4, CEA, et thrombospondine.

TITLE OF THE INVENTION***SPODOPTERA FRUGIPERDA* SINGLE CELL SUSPENSION CELL LINE****IN SERUM-FREE MEDIA, METHODS OF PRODUCING AND USING****RELATED APPLICATIONS**

Reference is made to U.S. applications Serial Nos. 09/169,178, filed October 8, 1998, 08/965,698, filed November 7, 1997, 08/120,601, filed September 13, 1993 (allowed), now U.S. Patent No. 5,762,939, 08/453,848, filed May 30, 1995 (allowed), 09/111,169, filed July 7, 1998, 08/850,366, filed May 2, 1997, and 08/430,971, filed April 28, 1995, each of which is hereby incorporated herein by reference. Similarly, all documents cited in the foregoing referenced applications and patent are hereby incorporated herein by reference. In addition, documents cited in the following text and documents referenced in documents cited in the following text are likewise incorporated herein by reference.

FIELD OF THE INVENTION

The present invention relates to a continuous insect cell line that grows as a single cell suspension in a culture media that is free of serum. Specifically, the cells are self-renewing; grow in suspension as single cells; replicate in a serum-free medium; are stable and can be propagated continuously for at least 6 months and 50 passages; are free of any detectable adventitious agents including mycoplasma, spiroplasma, and viruses, including retroviruses; support the replication of baculoviruses and produce high titers of virus; and produce foreign gene products for use in human and animal health applications.

BACKGROUND OF THE INVENTION

Insect cells that support the replication of baculoviruses were of interest initially for the study of the basic biology of insect viruses and in agricultural

5 use of baculoviruses for microbial pest control applications. Hink (Nature, 226:466-
467, 1970) reported the first continuous insect (Lepidoptera) cells that were shown to
10 support the replication of baculoviruses. Faulkner and Henderson (Virology, 50:920-
924, 1972) demonstrated that baculoviruses could be continuously propagated in a
5 stable insect cell line. More recently, with the development of baculovirus expression
15 vector systems, the need for insect cells that can be used for the commercial
production of human and animal health and diagnostic products has become
important.

20 Commonly used expression systems for the production of recombinant
10 DNA products are bacterial, yeast, insect and mammalian cells, and transgenic
animals. The general method is to introduce foreign genes into the cells or organisms
25 creating a transformed cell line or transgenic organism, which are unique for each
gene product. However, in the baculovirus expression system, foreign genes are
30 cloned into individual baculovirus vectors and a single insect cell line, susceptible to
15 baculovirus infection, can be used to produce an unlimited number of foreign gene
products.

35 The ideal insect cell line for use with baculovirus expression vectors
would replicate continuously in suspension as single cells making them ideal for use
40 in large-scale pharmaceutical bioreactors. The insect cells should also grow to high
20 density with a high degree of viability in a low-cost, serum-free medium and support
the replication of baculoviruses to high titers. The ideal insect cell line when infected
45 with a genetically engineered recombinant baculovirus would produce gene products
at high levels and produce those products consistently over many passages. The ideal
50 insect cell for the production of pharmaceutical products from baculovirus expression
25 vectors would also meet all regulatory requirements for identity and safety and be

5 readily expandable to large-scale bioreactors for the manufacture of pharmaceutical
products. Finally, due to the high cost of serum and the potential for contamination
10 with adventitious agents such as Bovine spongiform encephalopathy, a chronic
degenerative disease affecting the central nervous system of cattle (mad cow disease),
5 the ideal insect cell line would be stored and cultured in a serum-free medium. To
15 date, no such insect cell line with these ideal properties has been described. The
current invention has as an objective to provide an insect cell line, preferably such a
cell line with any or all of these ideal properties.

20 Baculoviruses are widely used for foreign gene expression in insect
10 cells (see, e.g., Smith, et al., U.S. Patent 4,745,051 (recombinant baculovirus) and
4,879,236; Summers and Smith. A Manual of Methods for Baculovirus Vectors and
25 Insect Cell Culture Procedures, May 1987, Texas A&M University; O'Reilly et al.
Baculovirus Expression Vectors A Laboratory Manual, 1994, Oxford University
30 Press; and references therein).

15 In particular, baculoviruses such as *Autographa californica* nuclear
polyhedrosis virus (AcNPV) are grown in established Lepidoptera insect cell lines
35 including ones derived from ovarian tissue of the fall armyworm (*Spodoptera*
frugiperda) and the cabbage looper (*Trichoplusia ni*) and midgut tissue from *T. ni*.
The cell lines in most common use to support AcNPV replication and production of
40 recombinant products are *S. frugiperda* IPLB-SF-21 (Vaughn, et al. In Vitro 13:213-
217, 1977) and *S. frugiperda* Sf-9 cells (Summers and Smith, *supra*), *T. ni* TN-368
45 cells (Ilinsk, *Ibid.* 1970) and *T. ni* BTI-TN-5-B1-4 cells (Granados, U.S. Patents Nos.
5,300,435, 5,298,418). The Sf-9 (ATCC CRL-1771) and BTI-TN-5-B1-4 (ATC, CRL
50 10859) cells were cloned in medium containing 10% or 8% Fetal Bovine Serum,
25 respectively. These and other insect cells can be adapted to commercial serum-free

5 medium, such as Sf-900 II SFM (Life Technologies, Grand Island, NY 14072), using
procedures known to those skilled in the art. Adapting cells repeatedly for use in the
10 manufacture of pharmaceutical products is not desirable in that it is time consuming,
may result in cells with differing properties with each adaptation, and the adapted
5 culture of cells would contain a variable level of residual serum.

15 In addition, the BTI-TN-5-B1-4 cells severely clump in suspension
with serum-free medium reducing its effectiveness as a host cell for foreign gene
productions with baculovirus vectors. The use of non-carboxylated sulfated
20 polyanions may help in overcoming this problem (Shuler and Dee, U.S. Patent
10 5,728,580, Mar. 17, 1998). However, sulfated polyanions can block the infection of
the cells with baculoviruses, thus complicating their use in the manufacture of
25 recombinant DNA gene products.

30 Insulin is an anabolic peptide hormone important in the regulation of
glucose metabolism. Insect and mammalian cells follow similar patterns of glucose
15 metabolism from glucose to pyruvic acid; therefore it is not surprising that insulin-like
peptides are produced in insects. The insect prothoracicotropic hormone (PTTH)
35 activates the prothoracic glands to produce the molting hormone ecdysone. The
PTTH bombyxin from the silkworm *Bombyx mori* has 40% homology with human
insulin. Bombyxin binds to specific receptors and induces morphological changes in
40 a *B. mori* cell line, specifically increasing cell size 1 – 2 weeks after exposure to a low
20 concentration of bombyxin (Tanaka, M. *et al.*, Regul. Pept. 57(3):311-318, 1995). *S.*
45 *frugiperda* Sf9 cells have receptors for the insulin-like peptide hormone bombyxin
and *B. mori* bombyxin binds with high affinity to receptors on *S. frugiperda* cells with
a dissociation constant of about 0.26 nM (Fillbright, et al., Eur. J. Biochem.
50 245(3):774-780, 1997). Although insulin is commonly used in growth media for
25

5 mammalian cells, it has not been described for use in media for insect cells. Goodwin
and Adams (Ed. Kurstak, Maramorosch, Dubendorfer, Invertebrate Systems In Vitro,
Elsevier/North-Holland Biomedical Press, 443-509, 1980) reported that 35 units/L of
10 insulin did not affect the growth of *Lymantria dispar* insect cells. In the present
5 invention insulin-containing serum-free medium was used in the generation of a new
15 *S. frugiperda* cell line.

Reference is also made to U.S. Patents Nos. 4,072,565, 5,135,866,
5,532,156, and 5,024,947. Inslow et al., U.S. Patent No. 5,024,947 relates to a serum-
20 free media for growth on insect cells and expression of products thereby, and either
10 individually or in any combination fails to teach or suggest the insect cell line or the
methods of making or using it of the present invention. Talbot et al., U.S. Patent No.
25 5,532,156 is directed to a hepatocyte cell line derived from the epiblast of pig
blastocysts and similarly either individually or in any combination fails to teach or
30 suggest the insect cell line or the methods of making or using it of the present
15 invention. Heifetz et al., U.S. Patent No. 5,135,866 provides a very low protein
nutrient medium for cell culture and likewise either individually or in any
35 combination fails to teach or suggest the insect cell line or the methods of making or
using it of the present invention. And, Weiss et al., U.S. Patent No. 4,072,565 relates
40 to the production of viruses in tissue culture without the use of serum, and either
20 individually or in any combination fails to teach or suggest the insect cell line or the
methods of making or using it in the present invention.

45 Thus, it is believed that heretofore, a cell line as described and claimed
herein, as well as the methods for making and using such a cell line, have not been
disclosed or suggested in the art.

50

55

OBJECTS AND SUMMARY OF THE INVENTION

It is an object of the invention to provide an insect cell line.

It is a further object of the invention to provide such a cell line that has any one or all of the following characteristics: replicate continuously in suspension as single cells, making them ideal for use in large-scale pharmaceutical bioreactors; grow to high density with a high degree of viability in a low-cost, serum-free medium; support the replication of baculoviruses to high titers; when infected with a genetically engineered recombinant baculovirus produce gene products at high levels and produce those products consistently over many passages; meet all regulatory requirements for identity and safety and be readily expandable to large-scale bioreactors for the manufacture of pharmaceutical products; and, able to be stored and cultured in a serum-free medium. Indeed, it is another object of the invention to provide an insect cell line having all of these characteristics.

Yet another object of the invention is to provide an insect cell line which overcome problems of prior insect cell lines, e.g., problems identified herein with prior insect cell lines.

It has surprisingly been found that a new insect cell line evolved or was derived from *Spodoptera frugiperda* Sf-9 cells in a serum-free medium containing added insulin. The new cell line, designated Sf900+ cells, have a phenotype and genotype unique from the parent Sf-9 cells. Further, it has surprisingly been found that the new cell line has the properties that make them ideal for use in the large-scale production of gene products for use in human and animal health. The cells grow continuously as single cell suspensions in a commercial serum-free medium, divide rapidly and maintain a high level of viability, and are highly permissive for infection

5 with baculoviruses producing high virus titers and high levels of recombinant gene
products. In addition, the Sf900+ cells meet the requirements for identity and safety
10 recommended for the manufacture of recombinant DNA gene products under the U.S.
current Good Manufacturing Practices (cGMP) specifications (Code of Federal
5 Regulations 21, Part 211, Current Good Manufacturing Practice for Finished
15 Pharmaceuticals, April 1, 1995). The Sf900+ cells are also in compliance with the
guidelines issued by the U. S. Food and Drug Administration Points to Consider for
Cell Lines used in the Production of Pharmaceutical Products (Points to Consider in
20 the Characterization of Cell Lines Used to Produce Biologicals, issued May 17, 1993,
10 U.S. Food and Drug Administration, Rockville, MD).

25 In one embodiment of this invention provides a new cell line that
replicates as a single cell suspension and is stable for 50 or more passages in serum-
free media.

30 Another embodiment of this invention provides a method to use the
15 new cell line for the production of high titers of wild-type and genetically engineered
recombinant baculoviruses.

35 Yet another embodiment of this invention provides the use of the cell
line to make baculovirus expression vectors and to produce high-titer stocks of
40 recombinant virus suitable for use in the production of recombinant gene products.

20 Still another embodiment of this invention provides the new cell line as
conforming to standard tests for identity and safety, whereby the new cell line can be
45 used in the commercial manufacture of pharmaceutical products.

50 And, another embodiment of this invention provides the use of the new
cell line for large-scale commercial production of recombinant gene products from
25 baculovirus expression vectors.

5 The inventive cell line is especially suited for practicing the teachings
of the applications and patent above-referenced under "Related Applications"; and,
10 this provides yet a further embodiment of the invention.

Further embodiments of this invention will be set forth in the
5 description that follows, and will become apparent to those skilled in the art and as
15 learned by the practice of the invention.

BRIEF DESCRIPTION OF THE DRAWINGS

The following Detailed Description, given by way of example, but not
20 intended to limit the invention to specific embodiments described, may be understood
10 in conjunction with the accompanying Figures, incorporated herein by reference, in
which:

25 Fig. 1 shows two typical growth curves of Sf900+ cells in serum-free
medium (Sf900+ cells were diluted into culture medium to 1.5×10^6 cell/ml and the
30 growth of the cells monitored every 24 hours for 4 days. Over the first 3 days the
15 cells doubled approximately every 22 – 24 hours to 9.0 and 9.6×10^6 cell/ml and over
98% of the cells remained viable. On the 4th day, cell growth was minimal and the
35 viability dropped to approximately 95%);

40 Fig. 2 shows that growth of Sf900+ cells over 50 passages in serum-
free culture medium (Sf900+ cells were split to 1.5×10^6 cells/ml every Monday,
20 Wednesday, and Friday. At each passage the cells were counted and the viability
measured. The graph shows the cell density at each day they were split (diamonds)
45 and the cell viability (squares). The cells reached densities of $5 - 11 \times 10^6$ cells/ml
and remained about 98% viable); and,

50 Fig. 3 shows that high titer of recombinant baculoviruses were
25 produced from Sf900+ cells that were between passage 5 and 55 from the Sf900+

Master Cell Bank (Sf900+ cells were infected with recombinant AcNPV baculovirus at an MOI of 1.0 and the infected cells were harvested at 48 – 72 hours post infection.

The infectious virus titers were measured in a standard plaque assay and found to be in the range of 0.6×10^6 to 2.2×10^8 pfu/ml).

DETAILED DESCRIPTION

The generation and use of recombinant baculovirus is known; for instance, from documents cited herein, including the above-referenced applications and patent.

Insect cells from *S. frugiperda* and other Lepidopteran insect species have been described in the literature and their general use to support the infection and replication of baculoviruses and the production of recombinant proteins is well known (see, e.g., Smith et al., U.S. Patent No. 4,745,051 (recombinant baculovirus); Richardson, C.D. (Editor), Methods in Molecular Biology 39, "Baculovirus Expression Protocols" Humana Press Inc. (1995)); Smith et al., "Production of Human Beta Interferon in Insect Cells Infected with a Baculovirus Expression Vector," *Mol. Cell. Biol.*, 3(12):2156-2165 (1983); Pennock et al., "Strong and Regulated Expression of *Escherichia coli* B-Galactosidase in Insect Cells with a Baculovirus vector," *Mol. Cell. Biol.*, 4(3):399-406. (1984); EPA 0 370 573, U.S. application Serial No. 920,197, filed October 16, 1986, EP Patent publication No. 265785). However, while *S. frugiperda* and other Lepidopteran insect species have been described in the literature, the literature fails to teach or suggest the insect cell line of the present invention. Nonetheless, the insect cell line of the present invention can be used instead of previously-described *S. frugiperda* and other Lepidopteran insect species, for instance, to support the infection and replication of baculoviruses and the production of recombinant proteins.

5 The expression of antigens in insect cells with baculovirus expression
vectors and their potential as vaccines is also well known. For example, Kamiya et
al., Virus Res. 32:375-379 (1994) relates to the protective effect of glycoproteins of
10 Newcastle disease virus expressed in insect cells following immunization with
5 recombinant glycoproteins. Hulst et al., J. Virol. 67:5435-5442 (1993) pertains to the
use of purified recombinant vaccine glycoprotein made in insect cells that protected
15 swine from infection with the hog cholera virus.

There are vaccines where whole insect cells or insect cell membrane
20 fractions containing a selected antigen are used. For example, McCown et al., Am. J.
10 Trop. Med. Hyg. 42:491-499 (1990), use *Spodoptera* insect whole cells expressing
Japanese Encephalitis Virus (JEV) glycoprotein E to immunize and protect mice
25 against JEV. Putnak et al., Am. J. Trop. Med. Hyg. 45:159-167 (1991), use a
microsomal membrane fraction of insect cells infected with a baculovirus expressing a
30 Dengue-1 envelope glycoprotein to immunize and protect mice against challenge with
15 Dengue-1 virus.

The insect cell line of the present invention is useful in the baculovirus
35 expression system, also known in the art as "BEVS", or as an adjuvant, as disclosed in
USSN 08/965,698, filed November 7, 1997.

In the baculovirus expression system, an inserted nucleic acid
40 molecule, e.g., the foreign gene, the heterologous or exogenous nucleic acid molecule,
20 for instance, DNA, is inserted into an insect virus vector, e.g., in a baculovirus vector,
which is then used to infect cells of the inventive cell line, for expression of the DNA.
45 The DNA preferably encodes an expression product comprising at least one epitope
of interest or antigen (including allergen).

50 Similarly, when the inventive insect cell line is used as an adjuvant, an
25

immunological or vaccine composition of the invention (including the cell line as an adjuvant) can include at least one epitope of interest or an antigen.

With respect to these terms, reference is made to documents cited herein and the following discussion, and generally to Kendrew, The Encyclopedia Of Molecular Biology, Blackwell Science Ltd., 1995 and Sambrook, Fritsch and Maniatis, Molecular Cloning, A Laboratory Manual, 2nd Ed., Cold Spring Harbor Laboratory Press, 1982 ("Maniatis et al., 1982").

An epitope of interest is an immunologically relevant region of an antigen or immunogen or immunologically active fragment thereof, e.g., from a pathogen or toxin of veterinary or human interest.

An epitope of interest can be prepared from an antigen of a pathogen or toxin, or from another antigen or toxin which elicits a response with respect to the pathogen or toxin, e.g., from an antigen of a human or veterinary pathogen or toxin, or from another antigen or toxin which elicits a response with respect to such a human or veterinary pathogen or toxin, such as, for instance: a Morbillivirus antigen, e.g., a canine distemper virus or measles or rinderpest antigen such as HA or F; a rabies glycoprotein, e.g., rabies glycoprotein G; an avian influenza antigen, e.g., turkey influenza HA, Chicken/Pennsylvania/1/83 influenza antigen such as a nucleoprotein (NP) or influenza A/Jalisco/95 H5 hemagglutinin; a human influenza antigen such as HA and/or NA; a bovine leukemia virus antigen, e.g., gp51, 30 envelope; a Newcastle Disease Virus (NDV) antigen, e.g., HN or F; a feline leukemia virus antigen (FeLV), e.g., FeLV envelope protein; a rous associated virus antigen such as RAV-1 env; matrix and/or preplomer of infectious bronchitis virus; a Herpesvirus glycoprotein, e.g., a glycoprotein, for instance from feline herpesvirus, equine herpesvirus, bovine herpesvirus, pseudorabies virus, canine herpesvirus, HSV, Marek's Disease Virus,

5 herpesvirus of turkeys (HVT) or cytomegalovirus; a flavivirus antigen, e.g., a
Japanese encephalitis virus (JEV) antigen, a Yellow Fever antigen, or a Dengue virus
antigen; a malaria (*Plasmodium*) antigen, an immunodeficiency virus antigen, e.g., a
10 feline immunodeficiency virus (FIV) antigen or a simian immunodeficiency virus
5 (SIV) antigen or a human immunodeficiency virus antigen (HIV) such as gp120,
15 gp160; a parvovirus antigen, e.g., canine parvovirus; an equine influenza antigen; a
poxvirus antigen, e.g., an ectromelia antigen, a canary pox virus antigen or a fowl pox
virus antigen; an infectious bursal disease virus antigen, e.g., VP2, VP3, VP4; a
20 Hepatitis virus antigen, e.g., HBsAg; a Hantaan virus antigen; a *C. tetani* antigen; a
10 mumps antigen; a pneumococcal antigen, e.g., PspA; a *Borrelia* antigen, e.g., OspA,
OspB, OspC of *Borrelia* associated with Lyme disease such as *Borrelia burgdorferi*,
25 *Borrelia afzelli* and *Borrelia garinii*; a chicken pox (varicella zoster) antigen.

Of course, the foregoing list is intended as exemplary, as the epitope of
30 interest can be derived from any antigen of any veterinary or human pathogen or
15 toxin; and, to obtain an epitope of interest, one can express an antigen of any
veterinary or human pathogen or toxin.

35 In regard to the foregoing lists, with respect to *Borrelia* DNA,
reference is made to: U.S. Patents Nos. 5,777,095, 5,688,512, 5,582,990, and
5,523,089; Bergstrom et al., Mol. Microbiol., 3(4):479-486 (April 1989); Johnson et
40 al., Infect. and Immun. 60:1845-1853 (1992); Johnson et al., Vaccine 13(12): 1086-
20 1094 (1995); and "The Sixth International Conference on Lyme Borreliosis: Progress
on the Development of Lyme Disease Vaccine," Vaccine, 13(1):133-135, 1995; and
45 PCT publications WO 90/04411, WO 91/09870, WO 93/04175, and 96/06165.

50 With respect to pneumococcal epitopes of interest, reference is made to
25 Briles et al. WO 92/14488 and U.S. Patents Nos. 5,804,193, 5,753,463, 5,728,387,

5 and 5,476,929.

With regard to influenza epitopes of interest and antigens, e.g., HA,
NA, and recombinant baculovirus expression thereof, useful in the practice of the
10 present invention, reference is made to Smith et al., U.S. applications Serial Nos.
5 08/120,601, filed September 13, 1993 (allowed and now U.S. Patent No. 5,762,939),
15 08/453,848, filed May 30, 1995 (allowed), and 08/430,971, filed April 28, 1995, as
well as to Johansson et al., "Supplementation of conventional influenza A vaccine
with purified viral neuraminidase results in a balanced and broadened immune
20 response," Vaccine 16(9/10): 1009-1015 (1998), Johansson et al., "Immunogenicity of
10 influenza A virus N2 neuraminidase produced in insect larvae by baculovirus
recombinants," Vaccine 9:841 (1995).

As to expression of adhesin and urease epitopes, chimeric proteins
thereof, and chimeric nucleic acid molecules encoding such, reference is made to
30 USSN 09/111,169, filed July 7, 1998. The insect cell line of the present invention is
15 useful in the recombinant baculovirus expression of adhesin, urease, epitopes thereof,
and chimeric proteins thereof.

With respect to DNA encoding epitopes of interest, which DNA can be
expressed via a baculovirus expression system and using the cell line of the invention,
attention is directed to documents cited herein, see, e.g., documents cited *supra* and
40 documents cited *infra*, for instance: U.S. Patents Nos. 5,174,993 and 5,505,941 (e.g.,
20 rabies glycoprotein (G), gene, turkey influenza hemagglutinin gene, gp51,30 envelope
45 gene of bovine leukemia virus, Newcastle Disease Virus (NDV) antigen, FeLV
envelope gene, RAV-1 env gene, NP (nucleoprotein gene of
Chicken/Pennsylvania/1/83 influenza virus), matrix and preplomer gene of infectious
50 bronchitis virus; HSV gD); U.S. Patent No. 5,338,683 (e.g., DNA encoding
25

5 Herpesvirus glycoproteins, *inter alia*); U.S. Patents Nos. 5,494,807, 5,756,103,
5,762,938 and 5,766,599 (e.g., DNA encoding antigens from rabies, Hepatitis B, JEV,
10 YF, Dengue, measles, pseudorabies, Epstein-Barr, HSV, HIV, SIV, EHV, BHV,
HCMV, canine parvovirus, equine influenza, FeLV, FHV, Hantaan, *C. tetani*, avian
5 influenza, mumps, NDV, *inter alia*); U.S. Patents Nos. 5,503,834 and 5,759,841 (e.g.,
15 Morbillivirus, e.g., measles F, hemagglutinin, *inter alia*); U.S. Patent No. 4,722,848
(e.g., HSV tk, HSV glycoproteins, e.g., gB, gD, influenza HA, Hepatitis B, e.g.,
HBsAg, *inter alia*); U.S. Patents Nos. 5,514,375, 5,744,140 and 5,744,141 (e.g.,
20 flavivirus structural proteins); U.S. Patent No. 5,766,598 (e.g., Lentivirus antigens
10 such as immunodeficiency virus antigens, *inter alia*); U.S. Patents Nos. 5,658,572 and
5,641,490 (e.g., IBDV antigens, *inter alia*); WO 94/16716 (e.g., cytokine and/or
25 tumor associated antigens, *inter alia*); U.S. Patents Nos. 5,688,920, and 5,529,780
(e.g., canine herpesvirus antigens), PCT publication WO 96/3941 (e.g.,
30 cytomegalovirus antigens); and U.S. Patents Nos. 5,756,101 and 5,766,597
15 (*Plasmodium* antigens).

As to antigens for use in vaccine or immunological, immunogenic or
35 antigenic compositions (which antigens can be from BEVS using the inventive cell
line or which compositions the cell line of the present invention can be an adjuvant),
reference is made to the documents cited herein and the discussion set forth herein
40 (see, e.g., documents cited *supra*) and also Stedman's Medical Dictionary (24th
20 edition, 1982), e.g., definition of vaccine (for a list of antigens used in vaccine
45 formulations; such antigens or epitopes of interest from those antigens can be used in
the invention, as either an isolated product employed with an inventive adjuvant or an
expression product of a recombinant insect virus or vector).

50
25 As to epitopes of interest, one skilled in the art can determine an

5 epitope or immunodominant region of a peptide or polypeptide and ergo the coding
DNA therefore from knowledge in the art, without undue experimentation, for
instance, from the amino acid and corresponding DNA sequences of the peptide or
10 polypeptide, as well as from the nature of particular amino acids (e.g., size, charge,
5 etc.) and the codon dictionary, *inter alia*; and, in respect to this, attention directed to
documents cited herein, including the aforementioned applications and patent.
Accordingly, without any undue experimentation, the present invention can be used to
practice recombinant baculovirus technology with the recombinant baculovirus
20 containing DNA for any desired epitope of interest or antigen of any human or
10 veterinary pathogen or toxin.

25 As a definitional matter, an immunological composition elicits an
immunological response - local or systemic. The response can, but need not be
protective. An immunogenic composition likewise elicits a local or systemic
30 immunological response which can, but need not be, protective. An antigenic
15 composition similarly elicits a local or systemic immunological response which can,
but need not be, protective. A vaccine composition elicits a local or systemic
35 protective response. Accordingly, the terms "immunological composition" and
"immunogenic composition" and "antigenic composition" include a "vaccine
composition" (as the three former terms can be protective compositions).

40 20 A better understanding of the present invention and of its many
advantages will be had from the following non-limiting Examples, given by way of
45 illustration.

EXAMPLES**EXAMPLE 1 - Sf900+****Establishment of a New Cell Line**

A new cell line was established from Lepidoptera, Noctuidae, *Spodoptera frugiperda* (Sf900+) that was evolved from the *S. frugiperda* Sf-9 insect cell line through multiple rounds of limiting dilution and selection in a commercial serum-free insect medium supplemented with human insulin. Specifically, Sf-9 cells (ATCC CRL-1771) were propagated to passage 41 (4 passages at Texas A&M University, College Station, TX; 15 passages at the ATCC, Rockville, MD; and an additional 22 passages at Protein Sciences Corporation, Meriden, CT) then stored in liquid nitrogen (Sf-9 Master Cell Bank No. 031793). A working bank of Sf-9 cells was produced and at passage 10, all of the serum-containing medium was removed by low speed centrifugation and the cells were suspended at a density of 0.5×10^6 cells/ml in commercial serum-free medium (Sf-900 SFM; Life Technologies, Grand Island, NY 14072). This procedure was repeated every 5 days and on the third passage recombinant human insulin (Sigma I-2767) was added at a concentration of $0.2 \mu\text{g/ml}$. The evolving cells were passaged an additional 34 times in 250 ml suspension cultures in Sf-900 SFM serum-free medium supplemented with $0.2 \mu\text{g/ml}$ human insulin. During the early passages cell death was 98% or more. This high level of cell mortality created the selective pressure needed for cells to undergo an evolutionary change.

It was surprisingly found that a new cell line, designated Sf900+ cells, had evolved with new and desirable properties. A Master Cell Bank was created with aliquots of Sf900+ cells in serum-free medium supplemented with $0.2 \mu\text{g/ml}$ insulin and 10% dimethyl sulfoxide (DMSO).

The surprising properties of the Sf900+ cell line include:

- 1) Sf900+ cells are genetically and morphologically distinct from the parent Sf9 cells,
- 2) Sf900+ cells replicate in serum-free medium,
- 3) Sf900+ cells grow as a suspension of single cells without significant clumping,
- 4) Sf900+ cells grow exponentially with a cell doubling time of 18 – 24 hours,
- 5) Sf900+ cells can be passed continuously for at least 6 months while maintaining a high level of viability (>98%),
- 6) Sf900+ cells are highly permissive to infection with *A. californica* NPV baculoviruses resulting in high titered virus stocks,
- 7) Sf900+ cells are useful for the production of recombinant DNA gene products following infection with baculovirus vectors,
- 8) Sf900+ cells are useful for the production and plaque-isolation of genetically engineered baculoviruses,
- 9) Sf900+ meet the general identity and safety requirements for cells set by government regulatory agencies, and
- 10) Sf900+ are suitable for the manufacture of biological pharmaceutical products following cGMP standards.

Deposited Material

Sf900+ insect cell line was deposited with the American Type Culture Collection (ATCC), 10801 University Boulevard, Manassas, VA 20110-2009, under the terms of the Budapest Treaty, under ATCC Designation (Accession No.) CRL-12579 on September 18, 1998 (ATCC CRL-12579).

Sf900+ Cell Line Safety

The safety of Sf900+ cell line was established following the recommendations of the Director, Center for Biological Evaluation and Research, Food and Drug Administration, Rockville, MD (Points to Consider in the Characterization of Cell Lines Used to Produce Biologicals, issued May 17, 1993, U.S. Food and Drug Administration, Rockville, MD). Safety tests were done including tests for sterility, tumorigenicity, and for contaminating mycoplasma, spiroplasma, and viruses. Studies to search for viruses in the Sf900+ cells included tests in insect and mammalian cell lines, embryonated eggs, and suckling mice; and to detect any contaminating retroviruses, assay for reverse transcriptase and electron microscopy. The Sf900+ cells are sterile, do not cause tumors to form in nude mice, and are free of any detectable adventitious agents including mycoplasma; spiroplasma; and viruses, including retroviruses.

Sf900+ Cell Line Identification

Light microscopy, karyology, and isoenzyme analysis were used to identify the new Sf900+ cell line. The cytoplasm of Sf900+ cells is lightly granulated and the nucleus usually contains several nucleoli. The Sf900+ cells are spherical with a mean diameter of 40 microns, approximately twice the diameter of Sf-9 cells. The wet biomass (weight of the cells following removal by centrifugation of the culture medium), when infected, is approximately 3-times greater than Sf-9 cells at a given cell density. The karyology of lepidopteran insect cells are well known to those skilled in the art as being polyploid with several hundred poorly defined chromosomes. Both the Sf-9 and Sf900+ cells have this characteristic chromosome

5 pattern and can be distinguished from mammalian cells, such as Vero monkey kidney
cells, which have a defined and limited number of chromosomes. Another method
commonly used to identify cell lines is to compare the relative mobility of certain
10 isoenzymes on protein gels. Approximately 10^7 Sf900+, Sf9, and the mammalian
5 Vero cells were prepared for isoenzyme analysis essentially as described by Corsaro
and Fraser (*Characterization of clonal population of Heliothis zea cell line IPLB-HA*
1075, *In Vitro Cell. Dev. Bio.* 23(12):855-862, 1987). The isoenzyme patterns of
Sf900+, Sf-9, and Vero cells were compared against the enzymes Lactate
20 Dehydrogenase (LDH), Isocitrate Dehydrogenase (ICD), Phosphoglucose isomerase
10 (PGI), and phosphoglucumutase (PGM) using the AuthentiKit System (Innovative
Chemistry, Inc., Marshfield, MA, 02050). The relative mobilities of the isoenzyme of
25 the insect cells were distinctly different than that of the mammalian Vero cells (Table
1). Sf900+ cells have a similar but distinct isoenzyme pattern compared to the parent
30 Sf-9 cells (Table 1), demonstrating that the Sf900+ cells are genetically different than
15 the parent Sf-9 cells.

TABLE 1

Mobility of Isoenzymes (millimeters)

Cell line	LDH	ICD	PGI	PGM
Sf-9	12.5	nd*	5.0	14.0
Sf900+	11.0	nd*	5.0	14.0
Vero	8.0/2.0	8.0	-2.0	6.0

*No enzyme detected.

20 Sf900+ Cell Growth Characteristic

50 The Sf900+ cells grow at 27° C – 28° C in a commercial serum-free

5 medium (Sf-900 SFM; Life Technologies, Grand Island, NY 14072) supplemented
with 0.2 μ M recombinant human insulin. Routinely the cells are maintained in
10 suspension cultures and are passed three times a week by dilution of the cells with
fresh culture medium to 1.5×10^6 cell/ml. Following each dilution of the Sf900+ cells
5 to 1.5×10^6 cell/ml their growth is exponential for 2 – 3 days. Sf900+ cells have a
15 doubling time of 18 – 24 hours and reach a cell density in 3 – 4 days of $6 - 12 \times 10^6$
cells/ml with >95% of the cells remaining viable (Figure 1).

Routinely Sf900+ cells are passed with fresh medium three times a
20 week (typically Monday, Wednesday, and Friday of each week). Under these
10 conditions Sf900+ cells grow from 1.5×10^6 cell/ml to $5 - 11 \times 10^6$ cell/ml and are
>95% viable (Figure 2). It has surprisingly been found that the growth of Sf900+
25 cells can be maintained for 50 passages or longer without a significant change in
growth characteristics (Figure 3).

30 Biomass of Baculovirus Infected Sf900+ Cells in Large-Scale Bioreactors

15 The ideal insect cell line for the production of desired protein products
would have a high biomass per unit volume of culture. If the proportion of the desired
35 protein relative to the total cell biomass is constant, then the higher the cell biomass,
the higher the yields of a desired product. The biomass of baculovirus-infected
Sf900+ and Sf9 cells produced in 50L bioreactors were compared and the data is
40 shown in Table 2.
20

When infected at a cell density of 1.5×10^6 cells/ml, the Sf900+ cells
45 had the desired property of producing an average biomass of 14.8g/l compared to only
5.4g/l from the Sf9 cells or almost 3 times the biomass. The neuraminidase and HIV-
1 gp160 gene products from the large-scale cultures were purified and used in several
50 Phase I and Phase II human clinical trials approved by the U.S. FDA.
25

Table 2.

Biomass of Sf900+ and Sf9 Cells Produced in 50L Bioractors

Run No.	Cell Type*	Cell Density	Volume (L)	Biomass (g)	Biomass (g/L)
9723	Sf900+	1.50E+06	45	525	11.7
9737	Sf900+	1.50E+06	40	697	17.4
9741	Sf900+	1.50E+06	45	795	17.7
9744	Sf900+	1.50E+06	45	567	12.6
Mean		1.50E+06	43.8	646	14.8
9505	Sf9	1.45E+06	46	238	5.2
9601-F601	Sf9	1.34E+06	45	239	5.3
9601-F602	Sf9	1.41E+06	46	246	5.3
9601-F603	Sf9	1.50E+06	46	259	5.6
Mean		1.43E+06	45.8	246	5.4

* Sf900+ cells were infected with a recombinant baculovirus engineered to express influenza neuraminidase (strain A/Johannesburg/33/94 and Sf9 cells were infected with a recombinant baculovirus engineered to express HIV-1 gp160. Both cultures were infected at a MOI of 1pfu/cell. There was no significant growth of the Sf900+ cells or the Sf9 cells following infection. Infected cells were harvested at about 72 hours post infection and separated from the culture medium by centrifugation. The supernatant was discarded and the weight of the wet cells was measured.

Lack of Cell Aggregation with Sf900+ Cells

The degree of aggregation of Sf900+ cells was measured at a low (1.38×10^6 cells/ml) and high (6.56×10^6 cells/ml) cell density. Sf900+ cells were counted using standard procedures in a hemocytometer. The number of aggregates with 5 or more cells in a clump and the number of viable and dead cells were recorded. The cell viability was >99% in both the low and high-density cultures. Only 1.4% and 1.3% of the cells were aggregated in the low and high density cultures respectively, demonstrating the surprising result that Sf900+ cells grow in serum-free medium

essentially as a single-cell suspension of cells. The fact that Sf900+ cells do not aggregate avoids the problem associated with adding reagents or chemicals to the culture to prevent aggregation. Any aggregation would severely reduce the productivity of the cells due to diffusional barriers for nutrients or by-products or due to reducing their accessibility to virus infection.

TABLE 3.

Aggregation of Sf900+ Cells at Low and High Cell Densities

	Low Density		High Density	
	Counts	Clumps	Counts*	Clumps
	130	1	149	1
	105	1	122	2
	157	4	124	1
	160	2	130	3
Mean	138	2	131	2
cells/ml	1.38×10^6		6.56×10^6	
%	1.4		1.3	

*(The high-density culture was diluted 1/5 with culture medium before counting.)

10 Replication of Baculoviruses in Sf900+ Cells

A noteworthy characteristic of the Sf900+ cells is that they produce very high titers of *A. californica* NPV baculovirus. For example, Sf900+ cells were seeded at 1.5×10^6 cells/ml and can be used for 50 passages or longer for baculovirus production. Figure 3 shows examples of the titers as measured in a standard plaque assay of baculoviruses observed in Sf900+ cells from passage 5 to passage 55.

Sf900+ cells were obtained from the Master Cell Bank and passed three times weekly for up to 55 passages. Cells from passages 5 to 55 were diluted to 1.5×10^6 cells/ml and infected with recombinant AcNPV baculoviruses at a multiplicity of infection (MOI) of 1.0. At 48 – 72 hours post infection, the cells were harvested and the cells removed by low speed centrifugation. The titers of recombinant baculovirus were

measured in a standard plaque assay. Very high virus titers of *A. californica* NPV of 0.6×10^8 to 2.2×10^8 plaque forming units (pfu) per milliliter of culture were generated in cells up to passage 55.

Production of Gene Products in Sf900+ Cells

The ideal insect cell line could be used to produce recombinant proteins from any genetic source and, ideally, high levels of the desired protein product would be produced in a biologically active form. To demonstrate that Sf900+ cells can produce wide range of foreign gene products, Sf900+ cells were infected at a density of $1.5 - 3.0 \times 10^6$ cells/ml at an MOI of 1.0 with various AcNPV expression vectors containing the genes listed in Table 3. The organism of origin for the foreign gene and specific genes were cloned into AcNPV expression vectors according to standard methods. The relative yields, protein modification, location in the cells, and physical and biological properties of the recombinant proteins are given. The yields of recombinant proteins were quantified using standard chemical and immunological methods and scored as low ($< 1\text{mg/l}$), moderate ($1 - 10\text{mg/l}$), or high ($10 - 1000\text{mg/l}$).

Specific Methods for Producing Gene Products in Sf900+ Cells:

Influenza Virus Hemagglutinins from H1, H2, H5, H7, and B strains

Reference is made to U.S. Patent No. 5,762,939 and to allowed U.S. application Serial No. 08/453,848, incorporated herein by reference, for a detailed description of the cloning, baculovirus expression, fermentation and purification procedures, for the production of influenza virus hemagglutinins. Thus, hemagglutinin is obtained with at least 95% purity.

Influenza Virus Neuraminidase

The sequence of the Influenza Virus Neuraminidase (NA) (strain

5 A/Johannesburg/33/94) is available from GenBank (accession no. U43425). The NA
gene was amplified by PCR from viral cDNA using primers designed against a
10 consensus sequence (made by aligning NA gene from GenBank) A 5' PCR primers
was made that began at the ATG start codon of the full-length protein. A 3' primer
5 was designed to terminate after the natural stop codon of the NA open reading frame.
15 After PCR amplification, the resulting NA gene fragment was inserted into the
pMGS3 baculovirus transfer plasmid using standard procedures (Sambrook, J, Fritsch,
E.F., and Maniatis, T. 1989. Molecular cloning: a laboratory manual. 2nd ed. Cold
20 Spring Harbor Laboratory Press, Cold Spring Harbor, NY). The resulting transfer
10 plasmid contained the coding region from NA downstream of the polyhedrin
promoter, flanked by AcNPV DNA from the EcoRI "I" fragment (Summers and
25 Smith 1987, *supra*). Confirmation of the correct NA coding sequence was determined
by DNA sequence analysis.

30 Genomic baculovirus DNA and the transfer plasmid containing the NA
15 gene were mixed, co-precipitated with calcium chloride, and Sf900+ cells were
transfected as described (Summers and Smith 1987, *supra*). Recombinant viruses
35 were identified by plaque morphology and several were further plaque purified.
Recombinant viruses capable of expressing NA in infected Sf900+ cells were
40 identified and used as baculovirus expression vectors to produce recombinant NA in
20 Sf900+ cells.

Sf900+ cells, at a cell density of 1.5×10^6 cells/ml are infected with the
45 baculovirus expression vector containing the NA gene at an MOI of 1.0. Sf900+ cells
are harvested by centrifugation 72 hours post infection. The cell pellet containing
RNA is stored at -70°C for further processing.

50
25 Product purification follows centrifugation, filtration and

5 chromatographic procedures analogous to those presented for influenza virus
hemagglutinin. Thus, NA can be obtained with at least 95% purity.

10 **Human Immuno-deficiency Virus, Type 1 (HIV-1) HIV-1 *env* gp120**

The sequence of the HIV-1 *env* gp120 (gp120) is available from
5 GenBank (accession no. M19921). The plasmid pNL4-3 (Adachi et al. J. Virol. 59:
15 284-291 (1986)) was graciously obtained from Dr. Malcolm Martin's laboratory. A
construct was made in which gp120's natural signal peptide was replaced by a
baculovirus signal peptide. A 5' PCR primer was made that began at the N-terminal
20 residue of the mature peptide. A 3' primer was designed to place a stop codon at the
10 end of the gp120 portion of the *env* open reading frame. After PCR amplification, the
resulting gp120 gene fragment was inserted into the pMGS12 baculovirus transfer
25 plasmid using standard procedures (Sambrook, J, Fritsch, E.F., and Maniatis, T. 1989.
Molecular cloning: a laboratory manual. 2nd ed. Cold Spring Harbor Laboratory
30 Press, Cold Spring Harbor, NY). The resulting transfer plasmid contained the coding
15 region from gp120 downstream of the polyhedrin promoter, flanked by AcNPV DNA
from the EcoRI "I" fragment (Summers and Smith 1987, *supra*). Confirmation of the
35 correct gp120 coding sequence was determined by DNA sequence analysis.

Genomic baculovirus DNA and the transfer plasmids containing the
40 gp120 gene were mixed, co-precipitated with calcium chloride, and Sf900+ cells were
20 transfected as described (Summers and Smith 1987, *supra*). Recombinant viruses
were identified by plaque morphology and several were further plaque purified.
45 Recombinant viruses capable of expressing gp120 in infected Sf900+ cells were
identified and used as baculovirus expression vectors to produce recombinant gp120
in Sf900+ cells.

50
25 Sf900- cells, at a cell density of 1.5×10^6 cells/ml are infected with the

5 baculovirus expression vector containing the gp120 gene at an MOI of 1.0. Sf900+
cells are harvested by centrifugation 72 hours post infection. The cell pellet is
discarded and the supernatant containing secreted recombinant gp120 is stored at 4° C
10 for further processing.

5 Product purification follows centrifugation, filtration and
15 chromatographic procedures analogous to those presented for influenza virus
hemagglutinin. Thus, HIV-1 *env* gp120 can be obtained with at least 95% purity.

Human Immuno-deficiency Virus, Type 1 (HIV-1) HIV *gag* p55

20 The sequence of the human (HIV-1) HIV *gag* (p55) is available from
10 GenBank (accession no. M15654). The p55 gene obtained as a plasmid containing
the BH10 clone of LAV/HTLV-III strain of HIV-1 (Hahn et al. Nature 312: 166-69
25 (1984)) was used as the template to amplify p55 coding sequences by PCR. A 5' PCR
primer was made that began at the ATG start codon of the full-length protein. A 3'
30 primer was designed to terminate after the natural stop codon of the p55 open reading
15 frame. After PCR amplification, the resulting p55 gene fragment was inserted into
pMGS3 baculovirus transfer plasmid using standard procedures (Sambrook, J, Fritsch,
35 E.F., and Maniatis, T. 1989. Molecular cloning: a laboratory manual. 2nd ed. Cold
Spring Harbor Laboratory Press, Cold Spring Harbor, NY). The resulting transfer
40 plasmid contained the coding region from p55 downstream of the polyhedrin
20 promoter, flanked by AcNPV DNA from the EcoRI "I" fragment (Summers and
Smith 1987, *supra*). Confirmation of the correct p55 coding sequence was determined
45 by DNA sequence analysis and compared to Ratner et al. Nature 313: 277-284 (1985).

Genomic baculovirus DNA and the transfer plasmids containing the
p55 gene were mixed, co-precipitated with calcium chloride, and Sf900+ cells was
50 transfected as described (Summers and Smith 1987, *supra*). Recombinant viruses
25

5 were identified by plaque morphology and several were further plaque purified.
Recombinant viruses capable of expressing p55 in infected Sf900+ cells were
10 identified and used as baculovirus expression vectors to produce recombinant p55 in
Sf900+ cells.

5 Sf900+ cells, at a cell density of 1.5×10^6 cells/ml are infected with the
15 baculovirus expression vector containing the p55 gene at an MOI of 1.0. Sf900+ cells
are harvested by centrifugation 72 hours post infection. The cell pellet is discarded
and the supernatant containing secreted recombinant p55 is stored at 4°C for further
20 processing.

10 Product purification follows centrifugation, filtration and
25 chromatographic procedures analogous to those presented for influenza virus
hemagglutinin. Thus, HIV gag p55 can be obtained with at least 95% purity.

CD4

30 The sequence of the human CD4 (CD4) is available from GenBank
15 (accession no. M12807). The CD4 gene isolated from H9 human T-cell line (ATCC
HTB 176) cDNA was used as a template to amplify CD4 coding sequences by PCR.
35 A construct was made in which CD4's natural signal peptide was replaced by a
baculovirus signal peptide and the natural transmembrane domain was removed. A 5'
40 PCR primer was made that began at the N-terminal residue of the mature peptide. A
20 3' primer was designed to terminate before the natural transmembrane domain and
insert a stop codon. After PCR amplification, the resulting CD4 gene fragment was
45 inserted into the pMGS12 baculovirus transfer plasmid using standard procedures
(Sambrook, J, Fritsch, E.F., and Maniatis, T. 1989. Molecular cloning: a laboratory
50 manual. 2nd ed. Cold Spring Harbor Laboratory Press, Cold Spring Harbor, NY). The
25 resulting transfer plasmid contained the coding region from CD4 downstream of the

polyhedrin promoter, flanked by AcNPV DNA from the EcoRI "I" fragment (Summers and Smith 1987, *supra*). Confirmation of the correct CD4 coding sequence was determined by DNA sequence analysis and compared to a published sequence (Maddon et al. Cell 42: 93-104 (1985)).

Genomic baculovirus DNA and the transfer plasmids containing the CD4 gene were mixed, co-precipitated with calcium chloride, and Sf900+ cells were transfected as described (Summers and Smith 1987, *supra*). Recombinant viruses were identified by plaque morphology and several were further plaque purified. Recombinant viruses capable of expressing CD4 in infected Sf900+ cells were identified and used as baculovirus expression vectors to produce recombinant CD4 in Sf900+ cells.

Sf900+ cells, at a cell density of 1.5×10^6 cells/ml are infected with the baculovirus expression vector containing the CD4 gene at an MOI of 1.0. Sf900+ cells are harvested by centrifugation 72 hours post infection. The cell pellet is discarded and the supernatant containing secreted recombinant CD4 is stored at 4°C for further processing.

Product purification follows centrifugation, filtration and chromatographic procedures analogous to those presented for influenza virus hemagglutinin. Thus, CD4 can be obtained with at least 95% purity.

Human Erythropoietin

The sequence of human erythropoietin (EPO) is available from GenBank (accession no. X02157). The human EPO gene isolated from a genomic library in bacteriophage Lambda EMBL-3 was used as template to amplify EPO coding sequences by PCR. A construct was made in which EPO's natural signal peptide was replaced by a baculovirus signal peptide. A 5' PCR primer was made that

5 began at the N-terminal residue of the mature peptide. A 3' primer was designed to
terminate after the natural stop codon of the EPO open reading frame. After PCR
10 amplification, the resulting EPO gene fragment was inserted into the pMGS12
baculovirus transfer plasmid using standard procedures (Sambrook, J, Fritsch, E.F.,
5 and Maniatis, T. 1989. Molecular cloning: a laboratory manual. 2nd ed. Cold Spring
15 Harbor Laboratory Press, Cold Spring Harbor, NY). The resulting transfer plasmid
contained the coding region from EPO downstream of the polyhedrin promoter,
flanked by AcNPV DNA from the EcoRI "T" fragment (Summers and Smith 1987,
20 *supra*). Confirmation of the correct EPO coding sequence (Jacobs et al. Nature 313
10 806-10 (1985)) was determined by DNA sequence analysis.

25 Genomic baculovirus DNA and the transfer plasmids containing the
EPO gene were mixed, co-precipitated with calcium chloride, and Sf900+ cells were
transfected as described (Summers and Smith 1987, *supra*). Recombinant viruses
30 were identified by plaque morphology and several were further plaque purified.
15 Recombinant viruses capable of expressing EPO in infected Sf900+ cells were
identified and used as baculovirus expression vectors to produce recombinant EPO in
35 Sf900+ cells.

40 Sf900+ cells, at a cell density of 1.5×10^6 cells/ml are infected with the
baculovirus expression vector containing the EPO gene at an MOI of 1.0. Sf900+ cells
20 are harvested by centrifugation 72 hours post infection. The cell pellet is discarded
and the supernatant containing secreted recombinant EPO ("rEPO") is stored at 4°C
45 for further processing.

50 Product purification follows centrifugation, filtration and
chromatographic procedures analogous to those presented for influenza virus
25 hemagglutinin. Thus, EPO can be obtained which is purified to substantial

5 homogeneity or to at least 95% purity. With respect to EPO, DNA encoding EPO and
substantial homogeneity of EPO, reference is also made to Lin, U.S. Patents Nos.
4,703,008, 5,441,868, 5,574,933, 5,618,698, 5,621,080, and 5,756,349. In addition,
10 reference is also made to Wojchowski et al., "Active Human Erythropoietin Expressed
5 in Insect Cells, Using a Baculovirus Vector: A Role For N-Linked Oligosaccharide",
15 *Biochimica et Biophysica Acta* 910:224-32 (1987), Quelle et al., "High-Level
Expression and Purification of a Recombinant Human Erythropoietin Produced Using
a Baculovirus Vector", *Blood*, 74(2):652-57 (1989), Quelle et al., "Phosphorylatable
20 and Epitope-Tagged Human Erythropoietins: Utility and Purification of Native
10 Baculovirus-Derived Forms", *Protein Expression and Purification* 3:461-69 (1992),
and U.S. Patent Nos. 5,322,837 and 4,677,195. In contrast to any prior EPO from
25 baculovirus expression, EPO in accordance with the present invention can be purified
to at least 95% purity or to substantial homogeneity; and, as indicated in Table 3 the
30 EPO in accordance with the present invention stimulates erythropoiesis.

15 As a particular purification procedure, centrifuged culture supernatant
containing rEPO is pH adjusted to pH 8.0 with Tris-base. Proteinaceous and non-
35 proteinaceous materials bind to precipitating salts, mainly calcium hydroxide, and are
removed by centrifugation while rEPO remains in the supernatant. The resulting
rEPO containing supernatant is diafiltered into 10mM Tris-Cl buffer pH 8.0
40

20 The diafiltered rEPO containing supernatant is applied onto DEAE
Sephacrose and equilibrated with 10mM Tris-Cl buffer pH 8.0. The rEPO binds
45 weakly and is recovered in the flow-through while contaminants remain bound to the
column. Diafiltration into low-conductivity buffer prior to anion-exchange
50 chromatography ensures stronger binding of contaminants and higher degree of
25 purification at this step.

5 The collected DEAE flow-through is diafiltered into 10 mM sodium malonate buffer
pH 6.0 and applied to CM Sepharose equilibrated with the 10 mM sodium malonate
10 pH 6.0 buffer. The rEPO binds to CM Sepharose while contaminants flow through
the column. The column is then washed with 10mM sodium malonate buffer pH 6.0
5 containing 100 mM NaCl, to further remove contaminants. To elute rEPO from the
column, a 10 mM sodium malonate buffer pH 6.0 containing 150 mM NaCl is used.

The eluant containing rEPO is applied to a second CM Sepharose
column equilibrated with 10 mM sodium malonate buffer pH 6.0. It is then washed
20 with 10 mM sodium phosphate buffer pH 7.0 and finally, rEPO is eluted in PBS (10
10 mM sodium phosphate, 150 mM NaCl).

The EPO expressed is glycosylated and has a molecular weight of
25 approximately 25 kD. The amino acid sequence is the same as or analogous to that
set forth in literature and patents cited herein. It is quite surprising that the EPO in
30 accordance with the present invention stimulates erythropoiesis as the inventive EPO
15 has glycosylation which does not include sialic acid residues, and there is no
O-glycosylation because the EPO is from baculovirus expression; and, any reported
35 recombinant EPO from baculovirus expression heretofore was reported as having no
such activity.

In particular, urinary EPO (also known as uEPO) and recombinant
40 EPO produced in mammalian cells are heterogeneously glycosylated with complex N-
20 and O-linked oligosaccharides, including sialic acid N-terminal residues, and are
acidic proteins, whereas EPO from recombinant baculovirus expression can have a
45 comparably simple saccharide constitution and relative homogeneity, with no sialic
acid residues, neutral high-mannose moieties predominating and the highly basic
50 charge density of EPO retained, because of the limited capacity of insect cells to
25

process N-linked oligosaccharides.

Certain literature such as Quelle et al., *Blood*, *supra*, at 656, indicates that EPO from expression by insect cells infected with recombinant baculovirus containing DNA coding for EPO is not biologically active due to the lack of sialic acid residues. Further, there is a body of literature asserting that EPO's "heavy glycosylation" and sialic acid residues are essential for biological activity, see, e.g., Marmont, *Tumori* 83(4 Suppl 2):S3-15 (1997), Morimoto et al., *Glycoconj J* 13(6):1013-20 (1996), Higuchi et al., *J. Biol. Chem.* 267(11):7703-9 (15 Apr 1992), Takeuchi et al., *Glycobiology* 1(4):337-46 (1991), Tsuda et al., *Eur. J. Biochem.* 188(2):405-11 (1990), Takeuchi et al. *J. Biol. Chem.* 265(21):12127-30 (1990), Fukuda et al., *Blood* 73(1):84-9 (1989); Matsumoto et al. *Plant Mol. Bio.* 27(6):1163-72 (1995) (EPO from tobacco cells lacking sialic acid residues lacked activity).

In contrast, the recombinant EPO of the present invention has an activity of at least 200,000 U/mg (indeed about 500,000 U/mg) and stimulates erythropoiesis. In further contrast to prior EPO, the EPO of the present invention can be isolated using anion exchange and cation exchange chromatography, as opposed to reverse chromatography (used for isolating prior EPO).

Thus, the recombinant EPO of the present invention is distinct from and surprisingly superior to prior EPO.

Thrombospondin

The sequence of the human thrombospondin (TSP) is available from GenBank (accession no. X14787). The human TSP gene graciously obtained as a plasmid containing full-length TSP cDNA from Dr. Noel Bauck's laboratory was used as the template to amplify TSP coding sequences by PCR. A construct was made in which TSP's natural signal peptide was replaced by a baculovirus signal peptide. A

5' PCR primer was made that began at the N-terminal residue of the mature peptide.

A 3' primer was designed to terminate after the natural stop codon of the TSP open reading frame. After PCR amplification, the resulting TSP gene fragment was inserted into the pMGS12 baculovirus transfer plasmid using standard procedures

(Sambrook, J, Fritsch, E.F., and Maniatis, T. 1989. Molecular cloning: a laboratory manual. 2nd ed. Cold Spring Harbor Laboratory Press, Cold Spring Harbor, NY). The resulting transfer plasmid contained the coding region from TSP downstream of the polyhedrin promoter, flanked by AcNPV DNA from the *EcoRI* "I" fragment (Summers and Smith 1987, *supra*). Confirmation of the correct TSP coding sequence was determined by DNA sequence analysis and compared with Hennessy et al. J. Cell Biol. 108: 729-736 (1989).

Genomic baculovirus DNA and the transfer plasmids containing the TSP gene were mixed, co-precipitated with calcium chloride, and Sf900+ cells were transfected as described (Summers and Smith 1987, *supra*). Recombinant viruses were identified by plaque morphology and several were further plaque purified. Recombinant viruses capable of expressing TSP in infected Sf900+ cells were identified and used as baculovirus expression vectors to produce recombinant TSP in Sf900+ cells.

Sf900+ cells, at a cell density of 1.5×10^6 cells/ml are infected with the baculovirus expression vector containing the TSP gene at an MOI of 1.0. Sf900+ cells are harvested by centrifugation 72 hours post infection. The cell pellet containing recombinant TSP is stored at -70°C for further processing.

Product purification follows centrifugation, filtration and chromatographic procedures analogous to those presented for influenza virus hemagglutinin. Thus, TSP having at least 95% purity can be obtained.

Carcinoembryonic antigen (CEA)

The sequence of the human Carcinoembryonic antigen (CEA) is available from GenBank (accession no. M15042). The Human CEA isolated from LS174T human colon adenocarcinoma cell line cDNA (ATCC CL188) was used as template to amplify CEA coding sequences by PCR. A construct was made in which CEA's natural signal peptide was replaced by a baculovirus signal peptide and the natural transmembrane domain was removed. A 5' PCR primer was made that began at the N-terminal residue of the mature peptide. A 3' primer was designed to terminate before the natural transmembrane domain and insert a stop codon. After PCR amplification, the resulting CEA gene fragment was inserted into the pMGS12 baculovirus transfer plasmid using standard procedures (Sambrook, J, Fritsch, E.F., and Maniatis, T. 1989. Molecular cloning: a laboratory manual. 2nd ed. Cold Spring Harbor Laboratory Press, Cold Spring Harbor, NY). The resulting transfer plasmid contained the coding region from CEA downstream of the polyhedrin promoter, flanked by AcNPV DNA from the EcoRI "I" fragment (Summers and Smith 1987, *supra*). Confirmation of the correct CEA coding sequence was determined by DNA sequence analysis.

Genomic baculovirus DNA and the transfer plasmids containing the CEA gene were mixed, co-precipitated with calcium chloride, and Sf900+ cells are transfected as described (Summers and Smith 1987, *supra*). Recombinant viruses were identified by plaque morphology and several were further plaque purified. Recombinant viruses capable of expressing CEA in infected Sf900+ cells were identified and used as baculovirus expression vectors to produce recombinant CEA in Sf900+ cells.

Sf900+ cells, at a cell density of 1.5×10^6 cells/ml are infected with the

5 baculovirus expression vector containing the CEA gene at an MOI of 1.0. Sf900+
cells are harvested by centrifugation 72 hours post infection. The cell pellet is
discarded and the supernatant containing secreted recombinant CEA is stored at 4°C
10 for further processing.

5 Product purification follows centrifugation, filtration chromatographic
procedures analogous to those presented for influenza virus hemagglutinin. Thus,
15 CEA having a purity of at least 95% can be obtained.

TABLE 4

Organism	Gene in AcNPV Vectors	Production of Gene Product	Modification; Location in Sf900+ Cells	Physical and Biological Properties
Influenza Virus	Hemagglutinins from H1, H2, H5, H7, and B strains	Moderate to High	Glycosylated; cytoplasmic membranes	66 – 70Kd, trimers; agglutinates red blood cells
	Neuraminidase	Moderate	Glycosylated; cytoplasmic membranes	60Kd, tetramers; with sialidase activity
Human Immuno-deficiency Virus, Type 1 (HIV-1)	HIV-1 <i>env</i> gp120	High	Glycosylated; secreted	110kD, binds with high affinity to human CD4 receptor
	HIV <i>gag</i> p55	High	Myristylated; secreted	55kD, forms virus-like particles
Human	CD4	High	Glycosylated; secreted	50kD, binds with high affinity to HIV-1 gp120
	Erythropoietin	High	Glycosylated; secreted	25kD, monomers; stimulates erythropoiesis
	Thrombospondin	High	Glycosylated; cytoplasmic membranes	180kD, Anti-angiogenic
	Carcinoembryonic antigen (CEA)	High	Glycosylated; secreted	120kD, induces anti-CEA immune responses in humans

EXAMPLE 2 - ADJUVANT USES

Sf900+ cells are used in accordance with USSN 08/965,698, filed November 7, 1997 as an adjuvant in immunological, immune or vaccine compositions. Advantages of Example 1 are observed.

EXAMPLE 3 - EXPRESSION USES

The BEVS is used with other exogenous DNA encoding an antigen or an epitope of interest from an antigen, such as an antigen aforementioned, e.g., adhesin and/or urease or epitope(s) thereof such as a chimeric protein of adhesin and urease or of an epitope of interest of each of adhesin and urease. The insect cell line used with the BEVS is the inventive Sf900+ cell line. The antigen or epitope of interest is expressed, and the advantages of Example 1 are observed.

The antigen or epitope is optionally thereafter formulated into a vaccine, immune or immunological composition for administration orally or intragastrically, or for parenteral (i.e., intramuscular, intradermal or subcutaneous) administration or for other orifice administration, e.g., perlingual (i.e., oral), intragastric, mucosal including intraoral, intraanal, intravaginal, and the like administration.

* * *

Having thus described in detail preferred embodiments of the present invention, it is to be understood that the invention defined by the appended claims is not to be limited to particular details set forth in the above description as many apparent variations thereof are possible without departing from the spirit or scope of the present invention.

Claims

30

35

40

45

50

55

WHAT IS CLAIMED IS:

1. Insect cell line Sf900+ (ATCC CRL-12579).
2. An insect cell line established from Lepidoptera, Noctuidae, *Spodoptera frugiperda* Sf-9 (ATCC CRL-1771) through multiple rounds of limiting dilution and selection in a serum-free insect medium supplemented with added human insulin.
3. The insect cell line of claim 2 obtained from passing Sf-9 cells for 41 passages to obtain a first working bank of cells; passing the first working bank of cells for an additional 10 passages and at passage 10 removing serum-containing medium to obtain a second working bank of cell; repeatedly suspending the second working bank of cells in serum-free medium until a third passage wherein insulin is added to the medium to obtain insulin-contacted cells; and, passing the insulin-contacted cells in insulin-containing serum-free medium for a further 34 passages.
4. The insect cell line of claim 2 having one or more or all of the following characteristics:
 - 1) cells which are genetically and morphologically distinct from the parent Sf9 cells,
 - 2) cells which replicate in serum-free medium,
 - 3) cells which grow as a suspension of single cells without significant clumping,
 - 4) cells which grow exponentially with a cell doubling time of 18 – 24 hours,
 - 5) cells which can be passed continuously for at least 6 months while

maintaining a high level of viability (>98%),

6) cells which are highly permissive to infection with *A. californica* NPV
baculoviruses resulting in high-titered virus stocks,

7) cells which are useful for the production of recombinant DNA gene
products following infection with baculovirus vectors,

8) cells which are useful for the production and plaque-isolation of genetically
engineered baculoviruses,

9) cells which meet the general identity and safety requirements for cells set
by government regulatory agencies, and

10) cells which are suitable for the manufacture of biological pharmaceutical
products following cGMP standards.

5. In a vaccine or immunological composition, wherein the
improvement comprises, as an adjuvant, insect cells from an insect cell line as
claimed in any one of claims 1, 2, 3, or 4.

6. In a baculovirus expression system wherein a recombinant
baculovirus comprises exogenous coding DNA, the improvement comprising
infecting insect cells from an insect cell line as claimed in any one of claims 1, 2, 3, or
4, with the recombinant baculovirus.

7. A method for obtaining an insect cell line comprising
subjecting Lepidoptera, Noctuidae, *Spodoptera frugiperda* Sf-9 (ATCC CRL-1771) to
multiple rounds of limiting dilution and selection in a serum-free insect medium
supplemented with added human insulin.

8. The method of claim 7 comprising:
passaging Sf-9 cells for 41 passages to obtain a first working bank of
cells;

passaging the first working bank of cells for an additional 10 passages
and at passage 10 removing serum-containing medium to obtain a second working
bank of cells;

repeatedly suspending the second working bank of cells in serum-free
medium until a third passage wherein insulin is added to the medium to obtain
insulin-contacted cells; and,

passaging the insulin-contacted cells in insulin-containing serum-free
medium for a further 34 passages.

9. Substantially pure, recombinant glycosylated erythropoietin,
produced by a baculovirus expression system in cultured insect cells, wherein said
erythropoietin has relative homogeneity or is purified to 95% or greater and said
erythropoietin stimulates erythropoiesis and has an activity of at least 200,000 U/mg.

10. The erythropoietin of claim 9 which has an activity of about
500,000 U/mg.

11. Substantially pure, recombinant glycosylated neuraminidase,
produced by a baculovirus expression system in cultured insect cells, wherein said
neuraminidase is purified to 95% or greater and said neuraminidase has sialidase
activity.

12. Substantially pure, recombinant glycosylated CD4, produced
by a baculovirus expression system in cultured insect cells, wherein said CD4 is
purified to 95% or greater and said CD4 is secreted and binds with high affinity to
HIV-1 gp120.

13. Substantially pure, recombinant glycosylated thrombospondin,
produced by a baculovirus expression system in cultured insect cells, wherein said
thrombospondin is purified to 95% or greater and said thrombospondin is anti-

5 angiogenic.

14. Substantially pure, recombinant glycosylated CEA, produced
by a baculovirus expression system in cultured insect cells, wherein said CEA is
10 purified to 95% or greater and said CEA induces an anti-CEA immune response in
5 humans.

15. A substantially pure, recombinant glycosylated erythropoietin,
produced by a baculovirus expression system in cultured insect cells, wherein said
erythropoietin has relative homogeneity or is purified to 95% or greater and said
20 erythropoietin stimulates erythropoiesis and has an activity of at least 200,000 U/mg
10 or of about 500,000 U/mg; or

a substantially pure, recombinant glycosylated neuraminidase,
25 produced by a baculovirus expression system in cultured insect cells, wherein said
neuraminidase is purified to 95% or greater and said neuraminidase has sialidase
30 activity;

15 a substantially pure, recombinant glycosylated CD4, produced
by a baculovirus expression system in cultured insect cells, wherein said CD4 is
35 purified to 95% or greater and said CD4 is secreted and binds with high affinity to
HIV-1 gp120; or

40 a substantially pure, recombinant glycosylated thrombospondin,
20 produced by a baculovirus expression system in cultured insect cells, wherein said
thrombospondin is purified to 95% or greater and said thrombospondin is anti-
45 angiogenic; or

a substantially pure, recombinant glycosylated CEA, produced
by a baculovirus expression system in cultured insect cells, wherein said CEA is
50
25 purified to 95% or greater and said CEA induces an anti-CEA immune response in

humans; or

a substantially pure, recombinant, mature, glycosylated
influenza hemagglutinin produced by a baculovirus expression system in cultured
insect cells, wherein said hemagglutinin is purified to 95% or greater and said protein
is immunogenic, and induces a protective immune response when used as a vaccine;
wherein the cultured insect cells are from an insect cell line as claimed in any
one of claims 1, 2, 3, or 4.
